

# Outline – If Time Permits

## ✚ Lecture V

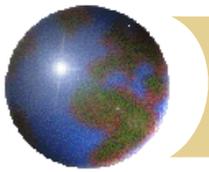

- ✚ Collider Detectors – Vertex and Tracking
- ✚ Electromagnetic Calorimetry
- ✚ Hadronic Calorimetry
- ✚ Radiation Field, Neutrons

# Particle ID

Particle type	Tracking	ECAL	HCAL	Muon
$\gamma$				
$e$				
$\mu$				
Jet				
Et miss				

Use subsystems – tracking, calorimetry (ECAL, HCAL) and muon detectors to identify the SM particles.

# Electromagnetic Calorimeter

## Physics driver: Z width

$$\Gamma_Z = 2.5 \text{ GeV}, M_Z = 91.2 \text{ GeV}$$

$$(dE/E)_{ECAL} < \Gamma_Z / (2.36M_Z) = 1.2\%$$

## EM Shower

$$t = L / X_0$$

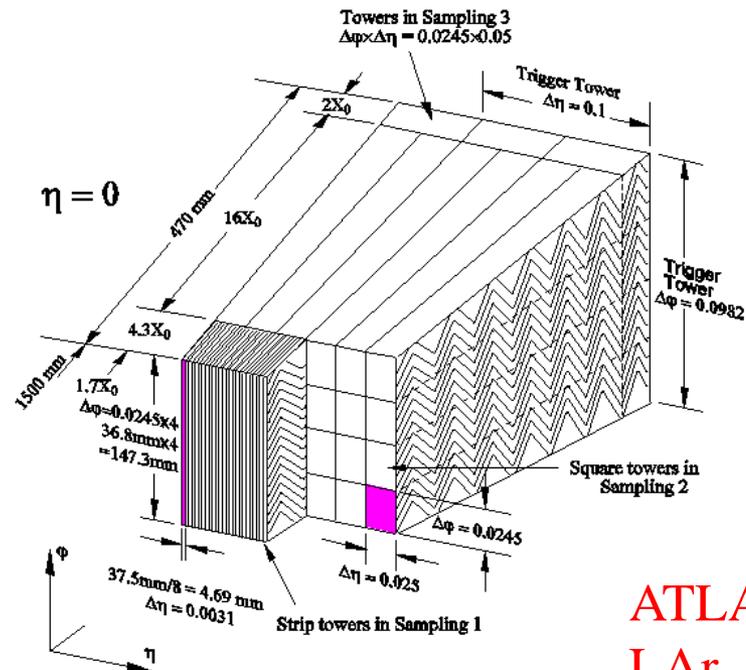

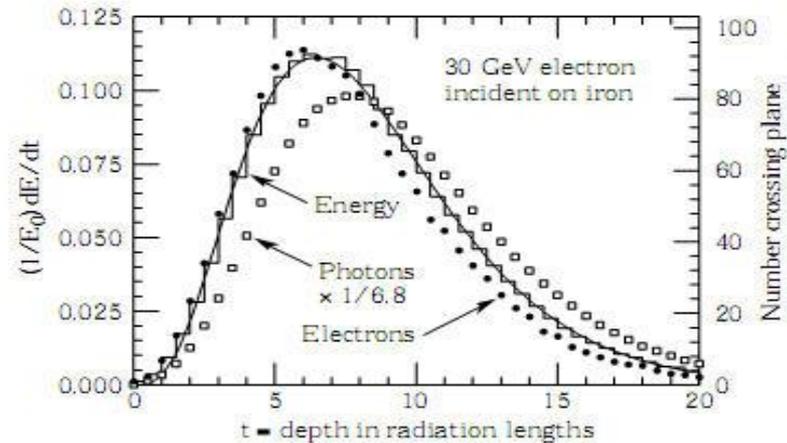

$$dE/dt = E_0 b (bt)^{a-1} e^{-bt} / \Gamma(a)$$

$$t_{\max} = (a-1) / b, b \sim 0.5$$

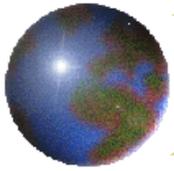

$$a \sim 1 + (\ln y) / 2$$

$$N_s \sim (E / E_c) \sim 2^{t_{\max}}$$

$$t_{\max} \sim \ln(E / E_c)$$

# Photons, Electrons and ECAL

$\gamma$

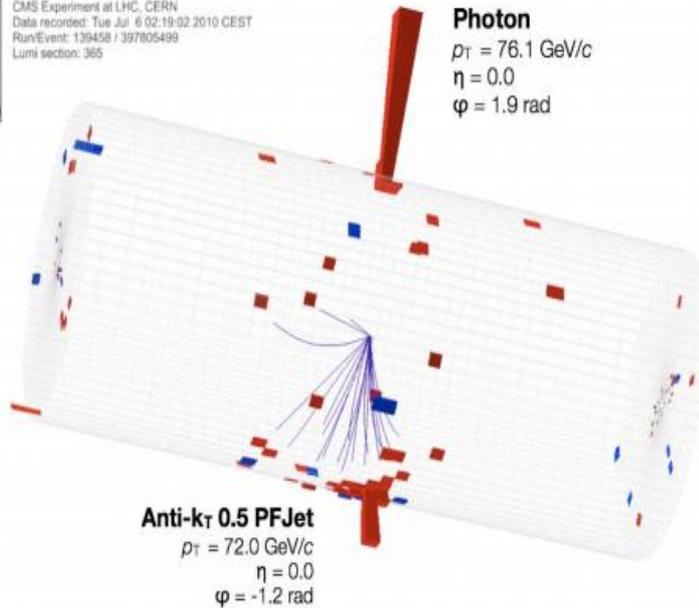

The CMS ECAL has a transverse segmentation  $\sim 1$  Moliere radius. Use that fine granularity for photon ID and for track matching in the case of electrons. ECAL energy resolution is very good for E/p matching of the e track. Tracker is best below  $\sim 20$  GeV, ECAL above.

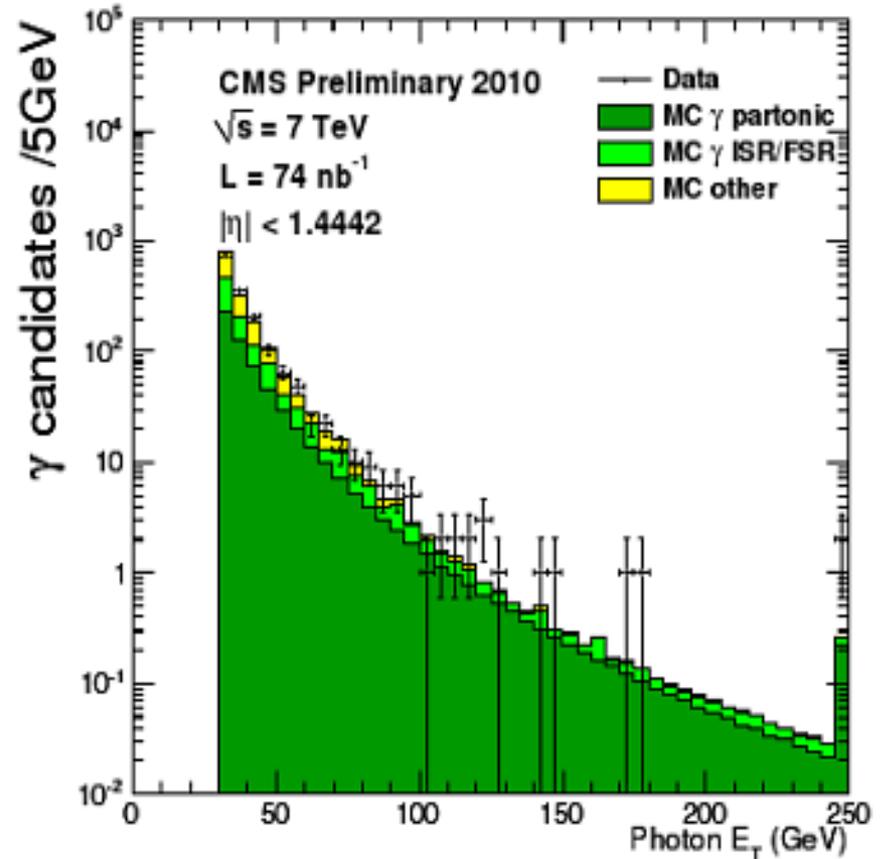

# Photon Commissioning

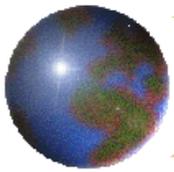

CMS Experiment at LHC, CERN  
Data recorded: Tue Jul 6 02:19:02 2010 CEST  
Run/Event: 139458 / 397805499  
Lumi section: 365

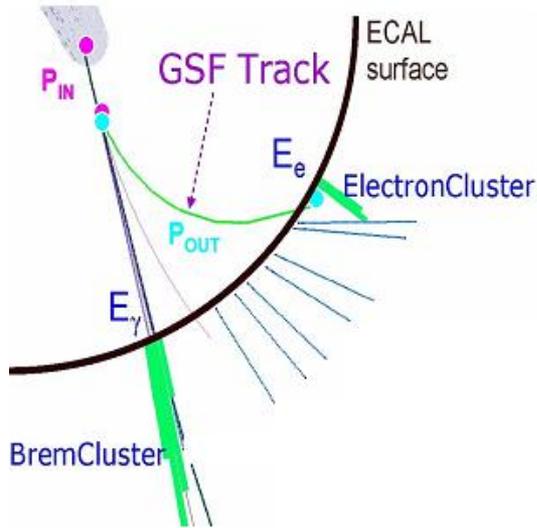

Clean photon + J events  
("Compton scattering with  
initial state gluons in the p).  
Photon spectrum quite clean for  
high Pt photons,  $> 100 \text{ GeV}$ .  
Data /Monte Carlo agreement  
is good.

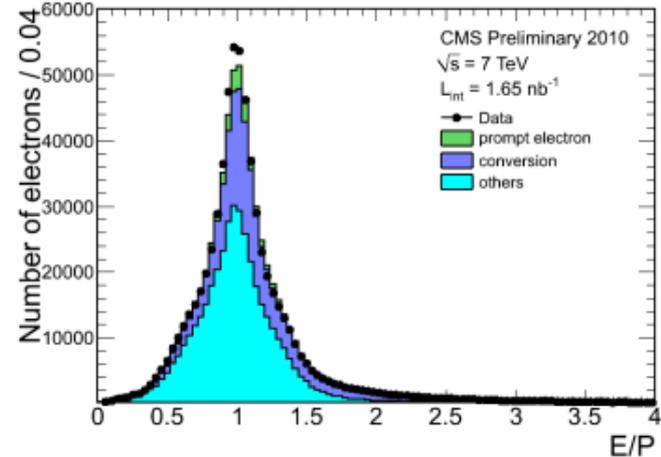

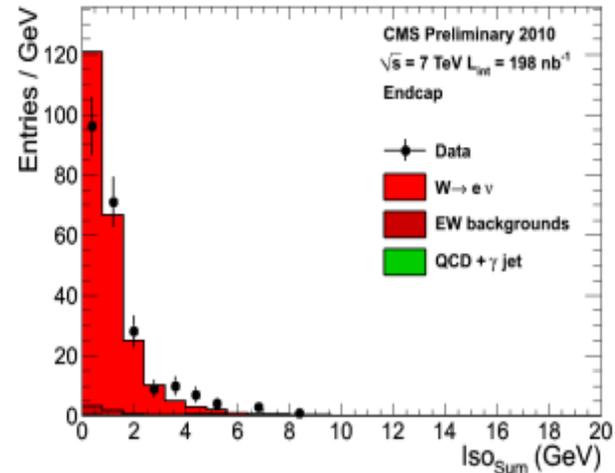

# Electrons – Track + ECAL

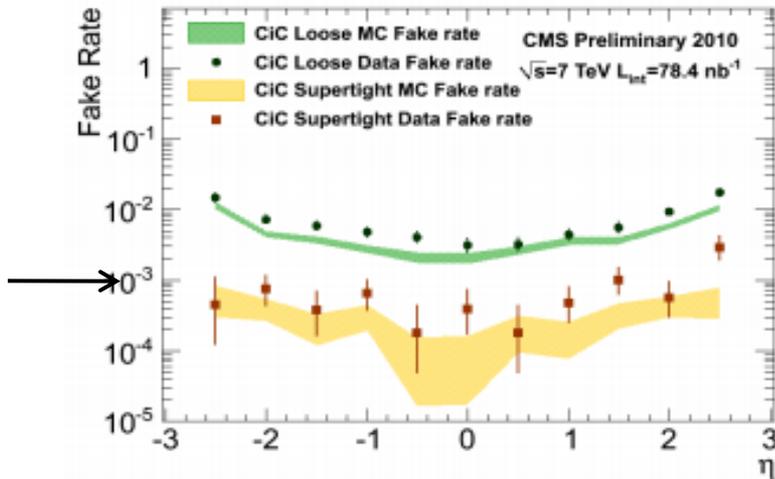

Understanding material of the CMS tracker is crucial. Bremsstrahlung in pipe and Si -> collect E in  $\phi$  Use E/p and isolation

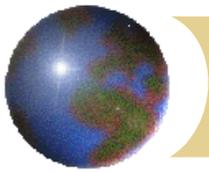

ECAL endcap

Eiso

# Muon Systems

$$b \rightarrow c + \mu + \nu$$

$$\sigma_{\mu} \sim 60 \quad \mu b$$

$$R_{\mu} = \sigma_{\mu} L \sim 0.6 \text{ MHz}$$

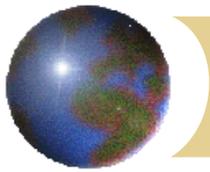

$$d\sigma / dP_{T\mu} = a e^{-P_{T\mu}/P_o}$$

$$e^{(\Delta P/P_o)/2}$$

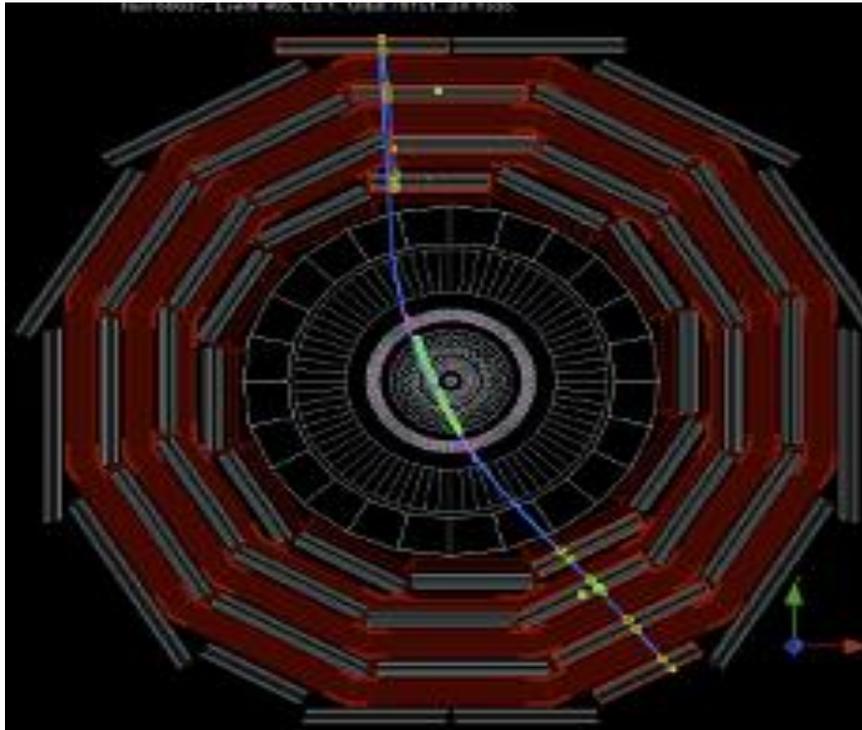

At low muon Pt the rate is dominated by HF decays

The muon trigger must have a sufficient resolution to reject these low momentum muons.

With a steeply falling spectrum, resolution is crucial in control of trigger rates.

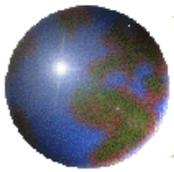

# Muon Commissioning

**CMS – DT/CSC in Fe  
return yoke => multiple  
scattering limited.**

Experience from  $\sim 10^9$  muons recorded before beam in the LHC. Muons up to 1 TeV in cosmics – gives experience with showering muons (critical energy). LHC “halo” also used for alignment of large  $|y|$  muon and tracking detectors - break alignment degeneracies.

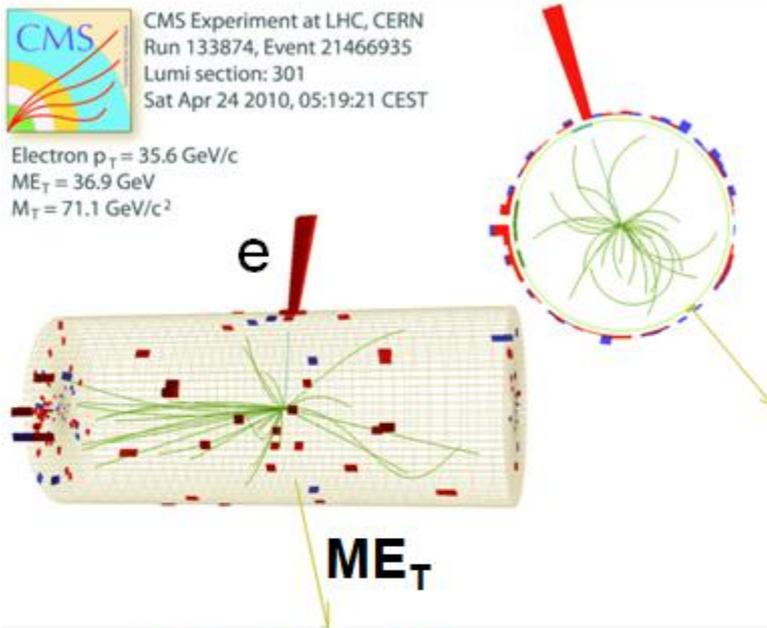

# EW Physics – W and Z, Electrons

CMS Experiment at LHC, CERN  
Run 133874, Event 21466935  
Lumi section: 301  
Sat Apr 24 2010, 05:19:21 CEST

Electron  $p_T = 35.6$  GeV/c  
 $ME_T = 36.9$  GeV  
 $M_T = 71.1$  GeV/c<sup>2</sup>

## W Candidate

$$W \rightarrow \ell + \nu$$

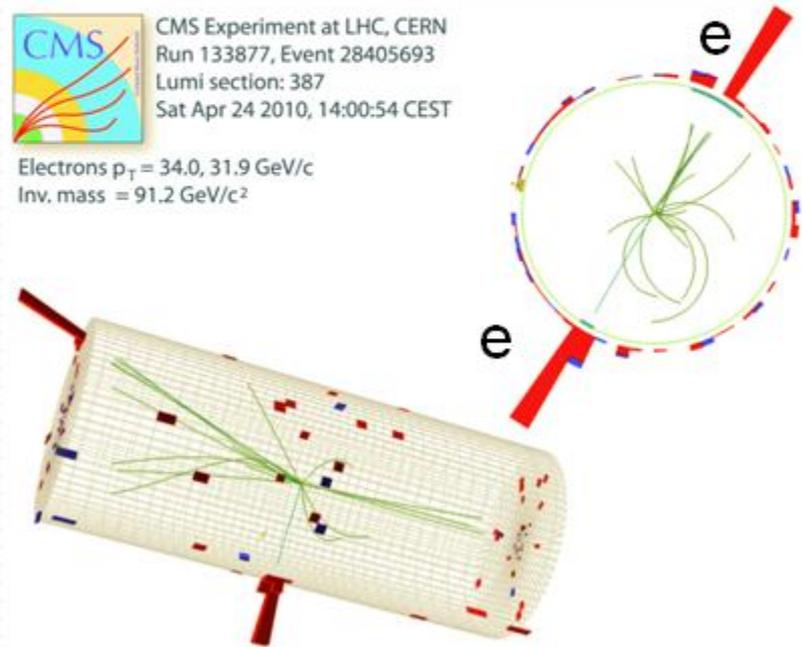

$$Z \rightarrow \ell^+ + \ell^-$$

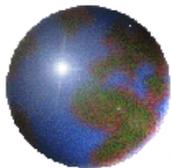

## Z Candidate

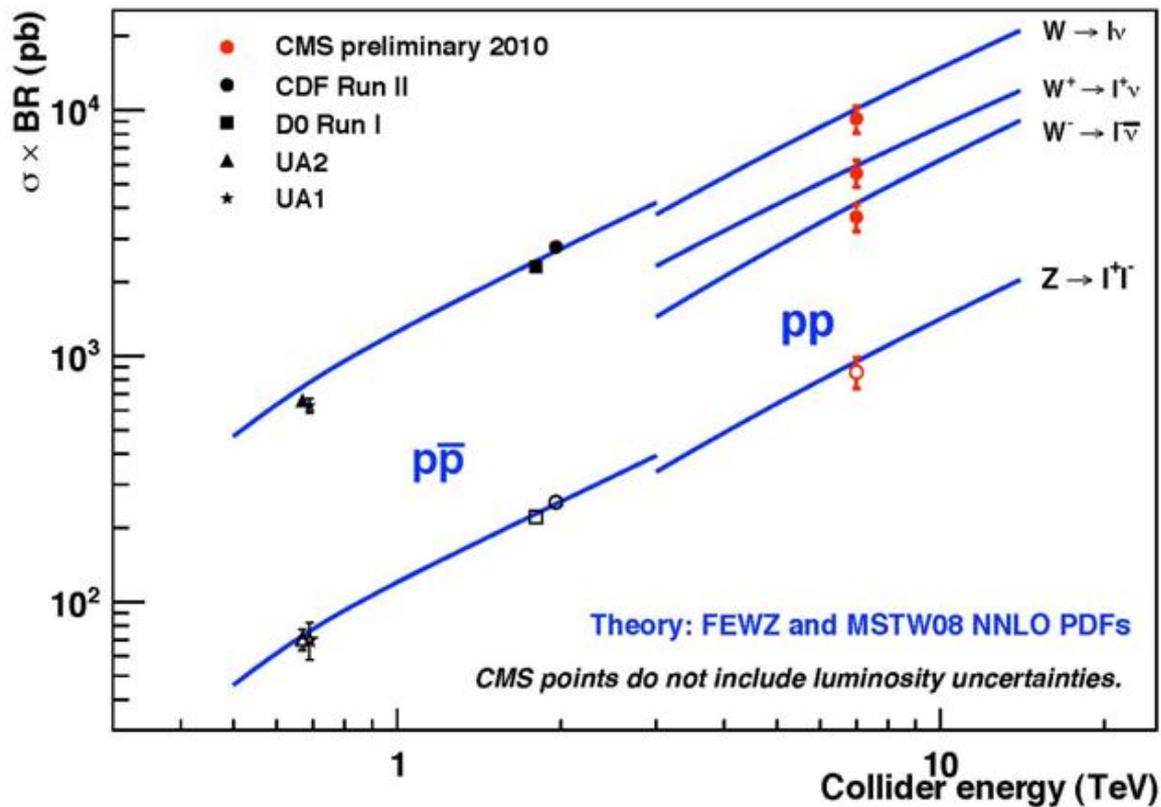

CMS Experiment at LHC, CERN  
Run 133877, Event 28405693  
Lumi section: 387  
Sat Apr 24 2010, 14:00:54 CEST

Electrons  $p_T = 34.0, 31.9$  GeV/c  
Inv. mass = 91.2 GeV/c<sup>2</sup>

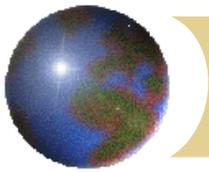

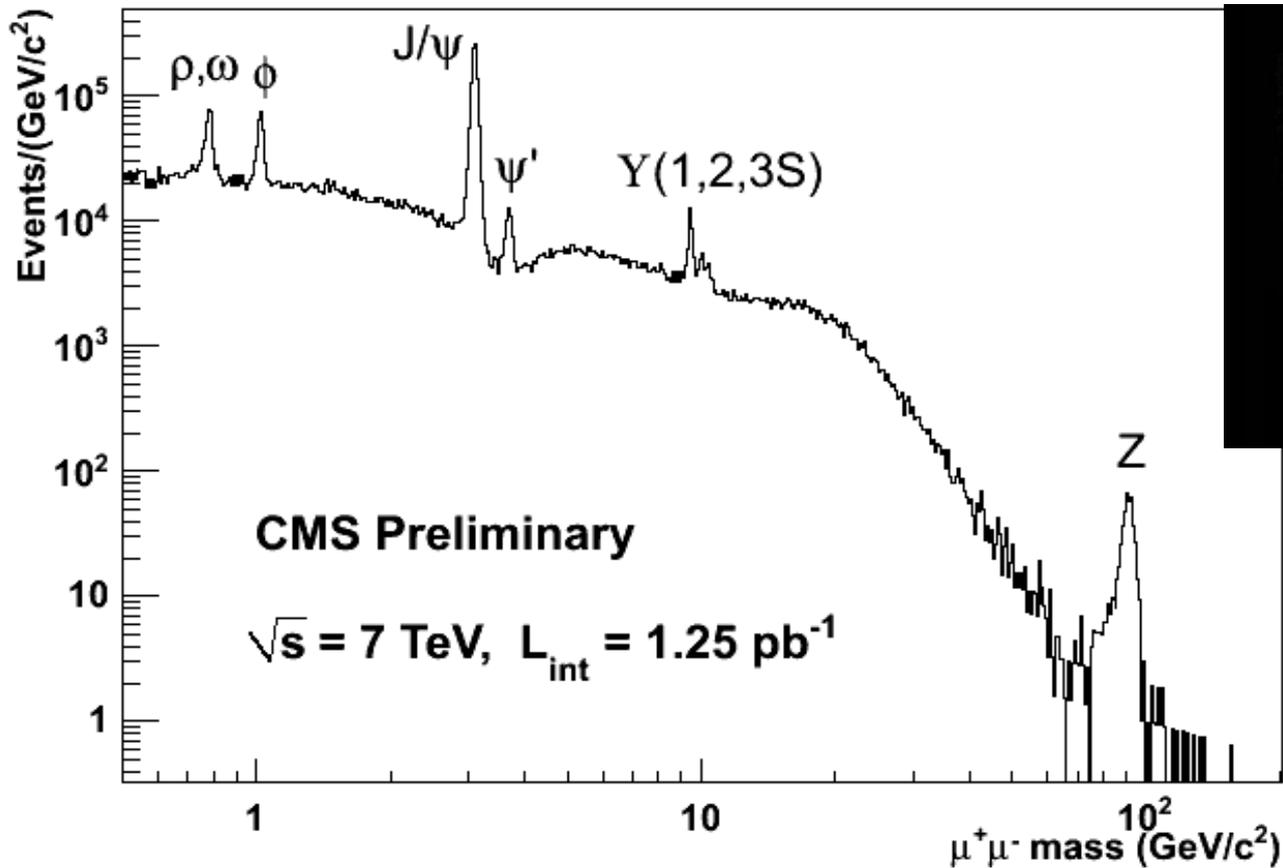

# EW Cross Sections

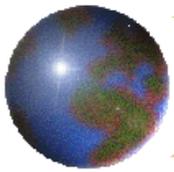

Luminosity error at  $\sim 4\%$ . Use W/Z calculations and van der Meer methods as a cross check.

# Dilepton “Standard Candles”

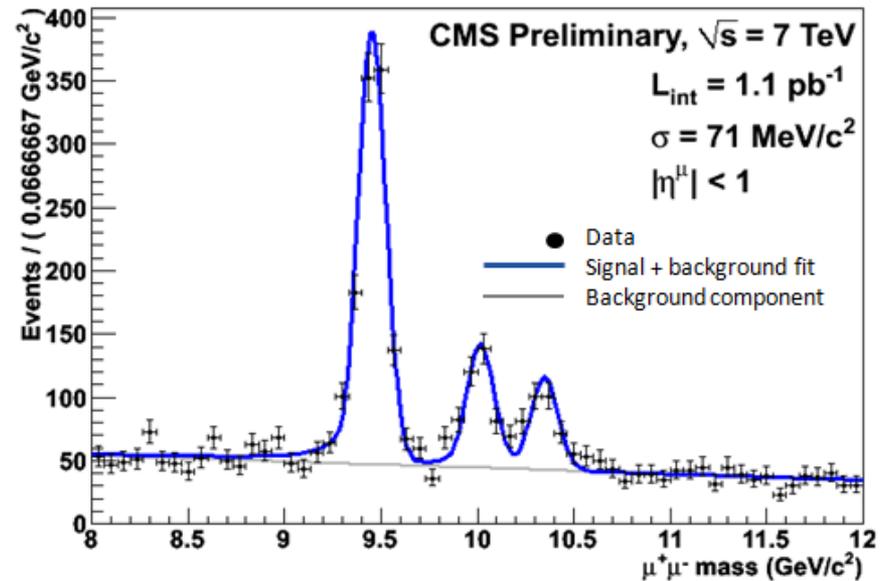

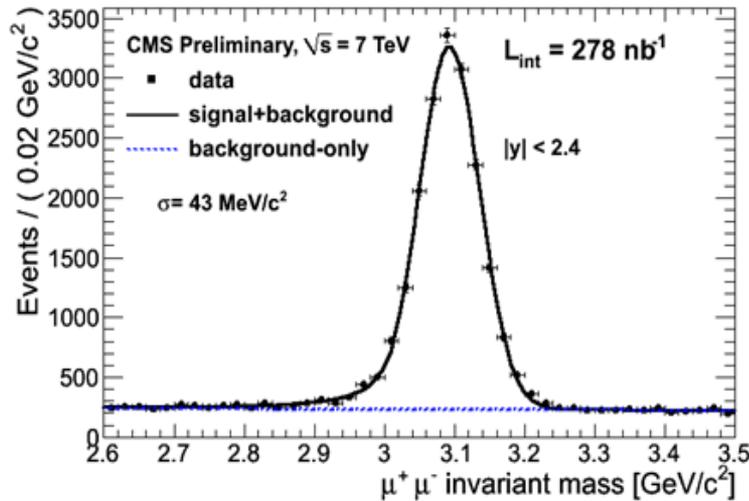

Use known resonances for mass scale, mass resolution and trigger/reco efficiency – “tag and probe”

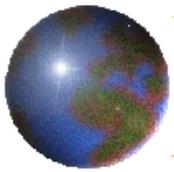

# Mass Scale and Resolution

$\psi$

$Y - \sigma / M \sim 0.7\%$

The several “standard candles” will light our way to new discoveries. Used to cross check the momentum resolution of the tracker and the energy resolution of the ECAL.

# Hadron Calorimeter - HCAL

Physics goal

$$W^+ \rightarrow u + \bar{d}, c + \bar{s}$$

–

$$\Gamma_W / M_W = 2.6\%$$

Hadronic W  
width

$$(dE / E)_{HCAL} \sim 1.1\%$$

How “deep”  
should the  
HCAL be?

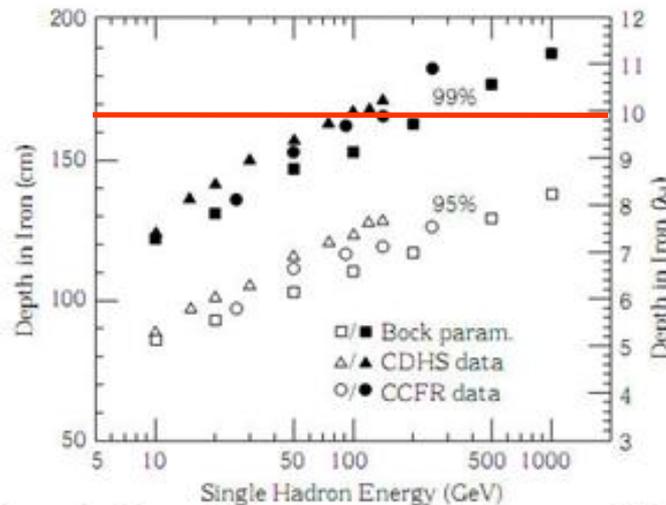

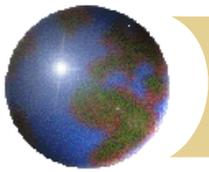

Figure 16: Depth needed for a shower energy containment of 95 % and 99 % as a function of hadron energy. Note the logarithmic dependence of depth on incident energy [8]

# E Resolution, Segmentation

$$E_{th} \sim 2m_{\pi} = 0.28 \text{ GeV}$$

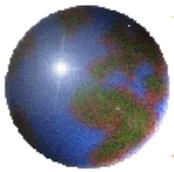

As with ECAL, there is a limit due to stochastic number of cascade particles. Analogue to critical energy is the threshold for pion production. This means that hadronic calorimetry will have worse resolution than ECAL – estimate 53% stochastic coefficient.

$$\delta\eta = \delta\phi = 0.094 \sim \lambda_o / r_H$$

$$(D_c = 6)(N_I = 25)(\delta\eta)^2 / 2\pi = 0.21$$

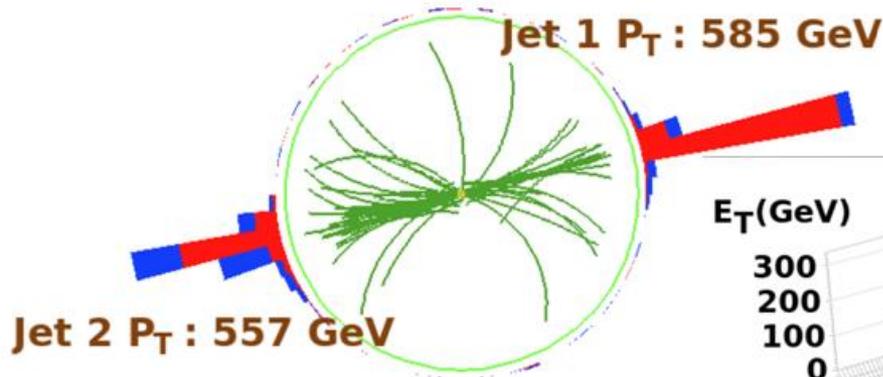

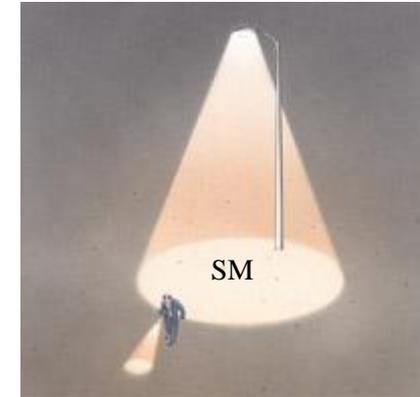

**3 depth segments  
– 13,470 channels  
in barrel**

Transverse size is also large,  $\sim$  inelastic interaction length. HCAL towers are coarser than ECAL --  $\sim 25$  ECAL towers = 1 HCAL tower. The probability to have a PU hit in a tower per bx is that factor higher.

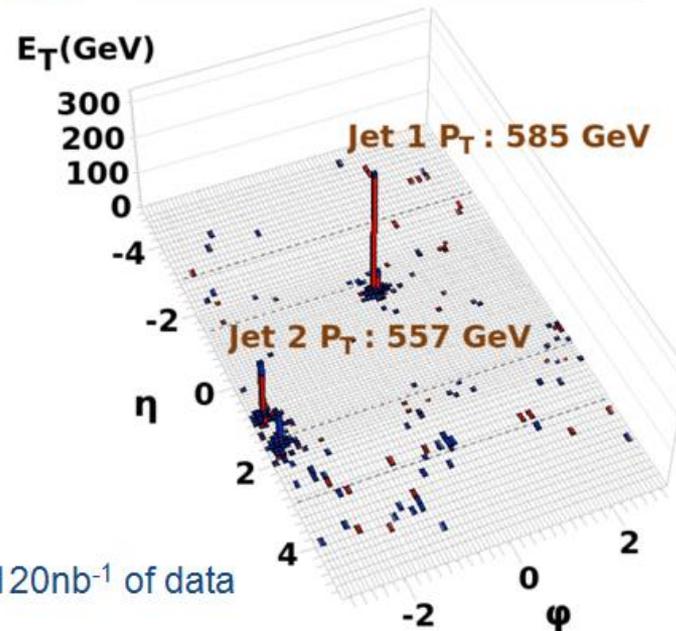

# Searches in Jet Events

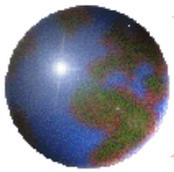

Having commissioned SM, go out from under the lamp post..... First event above the Tevatron kinematic limit.....

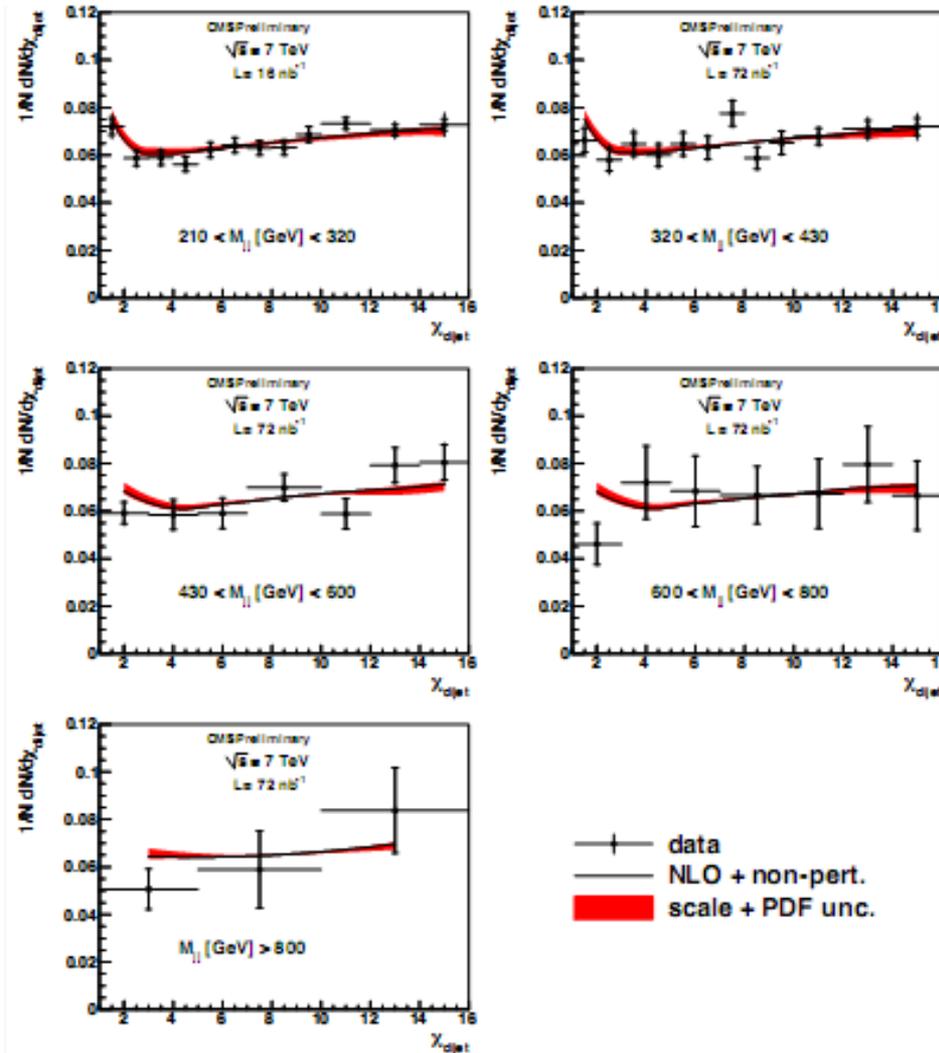

Run : 138919  
Event : 32253996  
Dijet Mass : 2.130 TeV

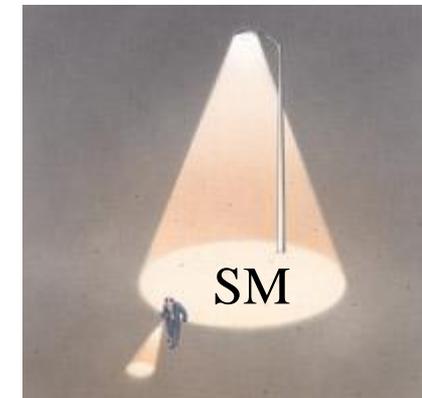

The highest mass dijet event in the first 120nb<sup>-1</sup> of data

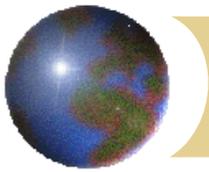

# Jet Angular Distributions

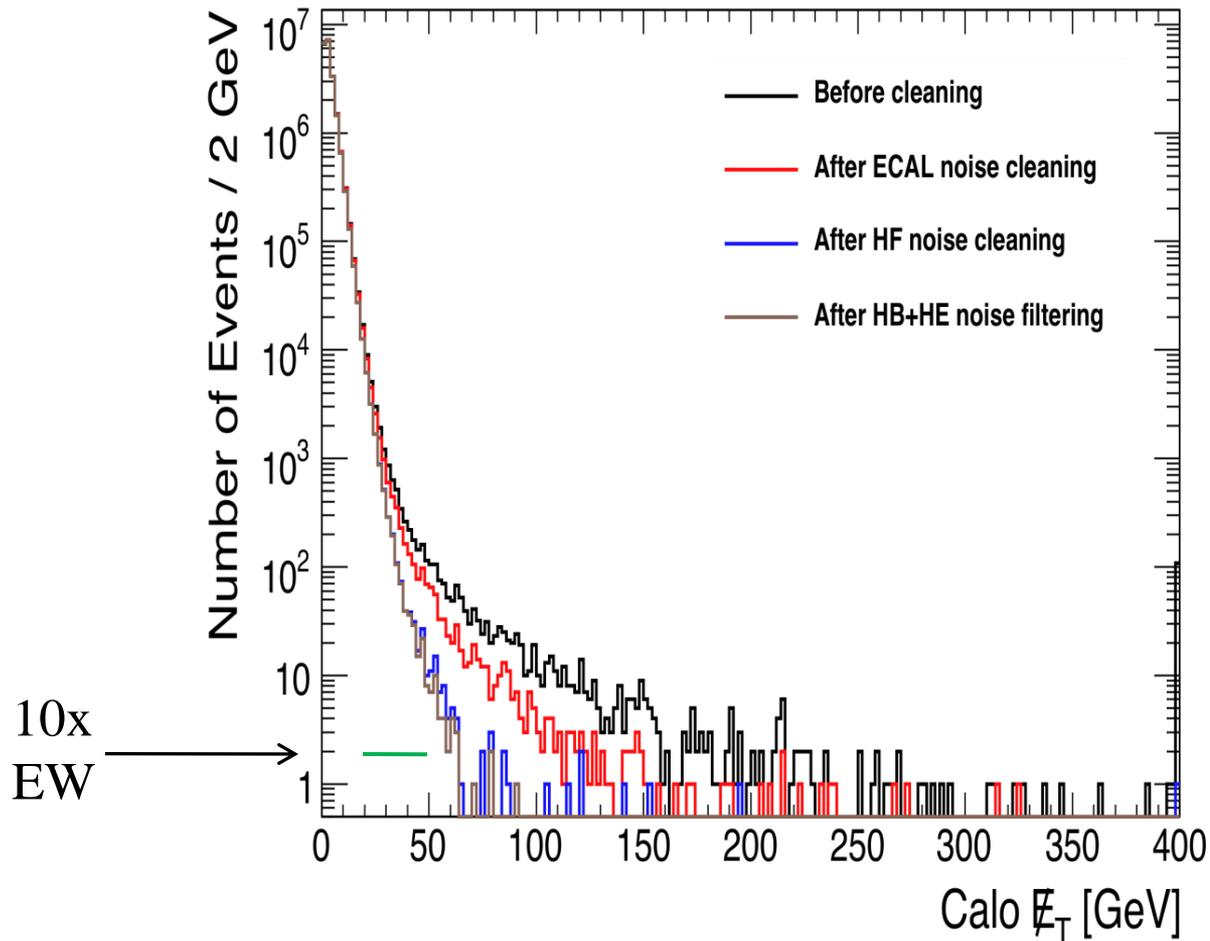

Look for more central, S wave, BSM effects. SM is t channel dominated  $\rightarrow$  flat  $\chi$  distribution.

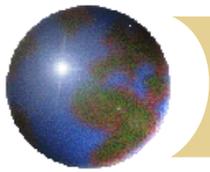

# MET – “Tail” and Noise Filtering

MB events :  
The MET noise filtering greatly reduces the tail. An irreducible floor is set by the EW processes, which are  $\sim 10^7$  times smaller in cross section than the inclusive MB events.

MET commissioned to  $\sim$  EW scale –  $\nu_e$ ,  $\nu_\mu$ ,  $\nu_\tau$

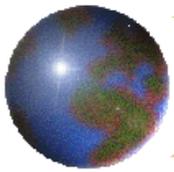

# Pileup/Fragmentation and Jets

As the LHC luminosity increases the pileup of events becomes more difficult. Jet fragmentation favors low energy particles. These become hard to distinguish from the particles from minimum bias events – use PF and vertex sorting for the charged particles. A jet ( $R = 0.5$ ) has  $N_I D \langle P_T \rangle / 2\pi \sim 28.6$  GeV of pileup pions which need to be removed.

$$D(z) \sim (1-z)^a / z$$

$$F \sim 1 - (1 - z_{\min})^{a+1}, \quad z_{\min} = (p_{had})_{\min} / P_{jet}$$

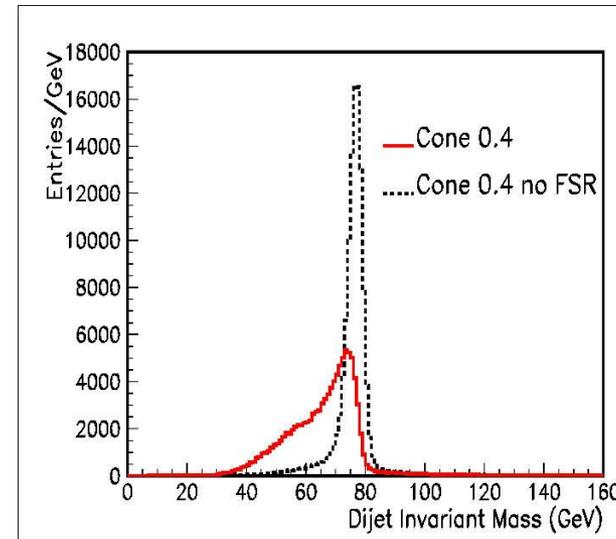

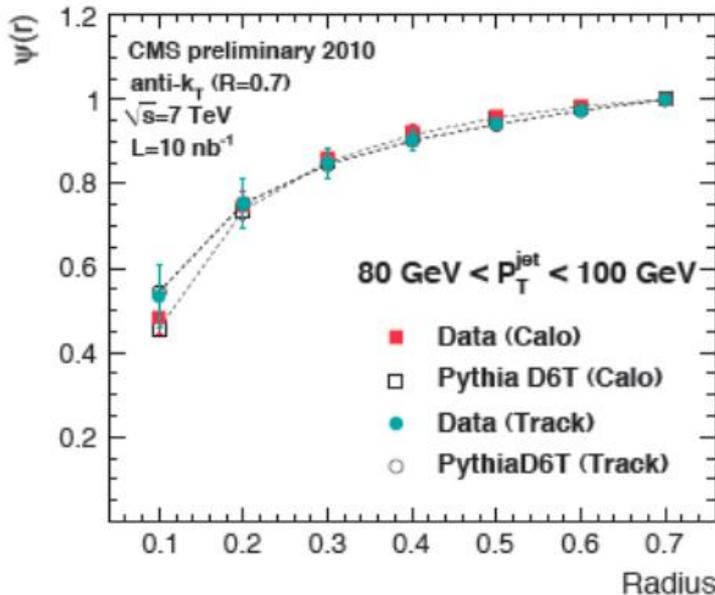

A 50 GeV jet has  $\sim 45\%$  of its energy carried by hadrons with momenta less than 5 GeV and  $\sim 12\%$  carried by hadrons with momenta less than 1 GeV. Thus the soft hadrons from the jet are easily confused with the soft pions from the pileup which then limits the achievable jet energy resolution.

# FSR – Jet Spectroscopy.

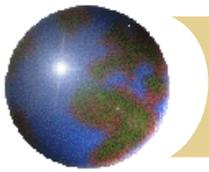

$$R = \sqrt{\delta\eta^2 + \delta\phi^2}$$

A “cone size” of  $\sim 0.5$  is needed to contain most of the jet energy - fluctuations

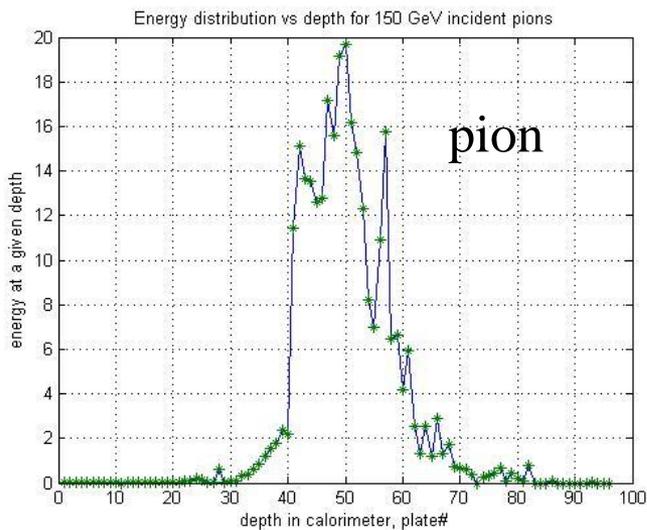

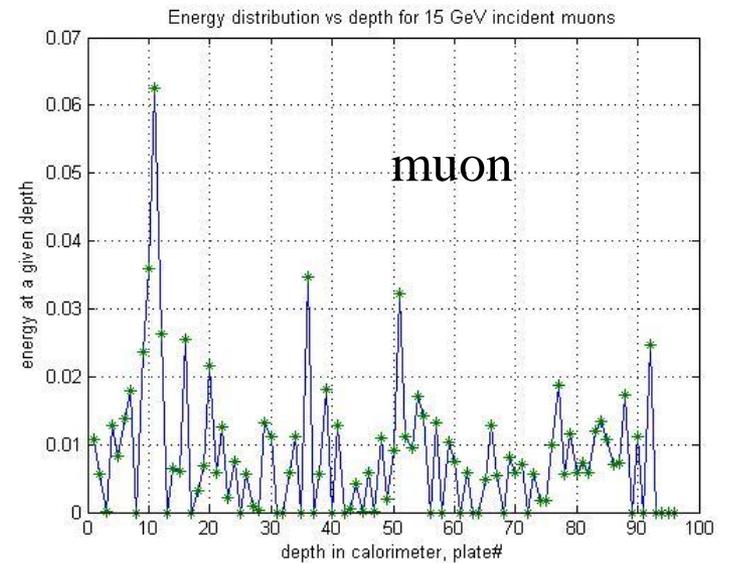

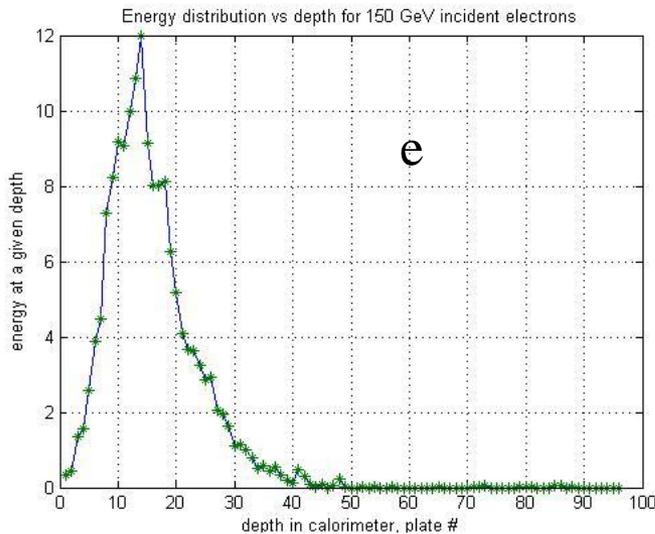

$$fract \sim (\alpha_s / \pi)[3 \log(R) + 4 \log(R) \log(2\varepsilon) + \pi^2 / 3 - 7 / 4]$$

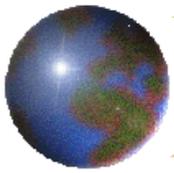

A 10 % radiation of the total jet energy outside a cone of  $R = 0.5$  occurs  $\sim 12.5$  % of the time.  
Gluon ISR and FSR is a limitation.

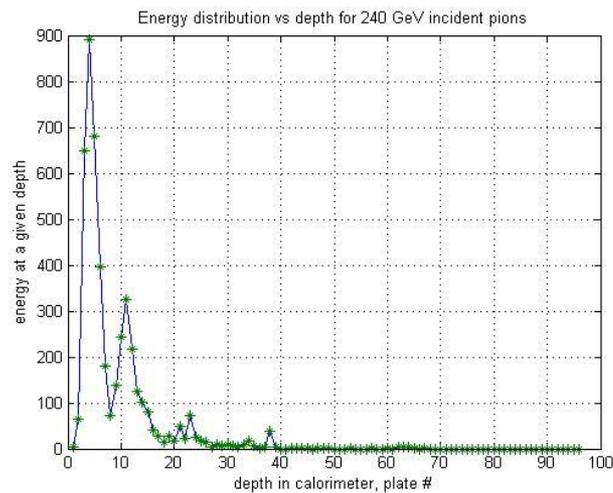

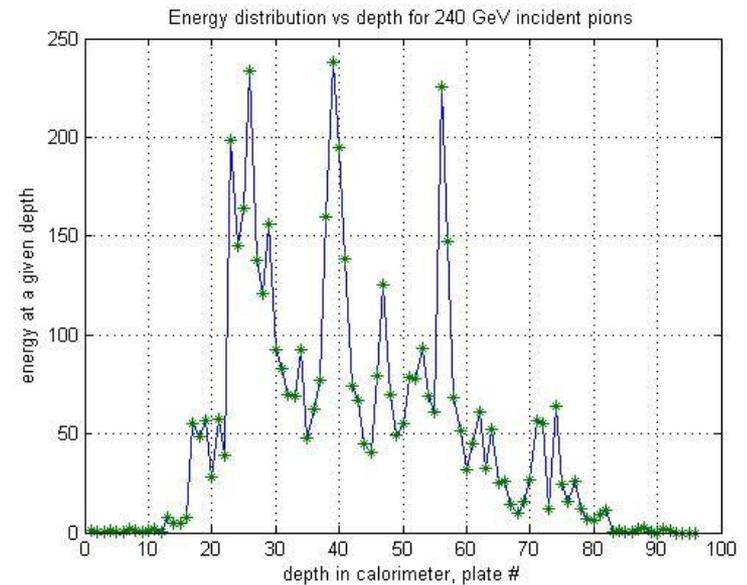

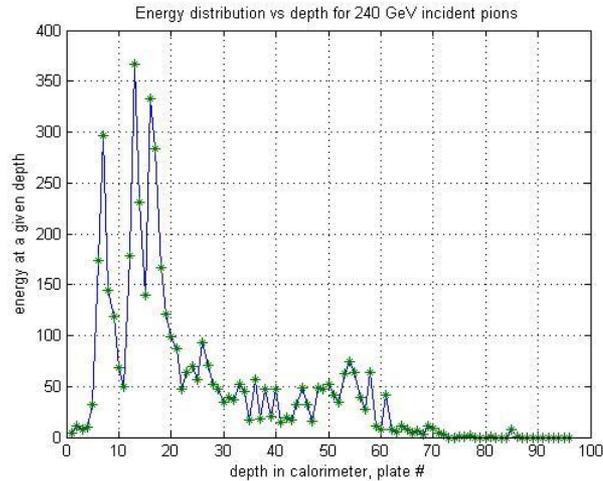

# Demo - Calorimetry - I

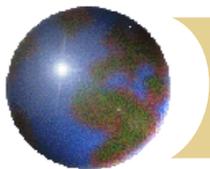

This is a “classical”  
ECAL+HCAL. Test beam data  
where each sampling layer is  
read out.

# Demo - Calorimetry - II

Pions incident on a homogeneous Pb calorimeter. This array has a large  $X_0$  to interaction length ratio so that the neutral pions from the sequential hadronic interactions are quite visible.

# Particle Flow and Calorimetry

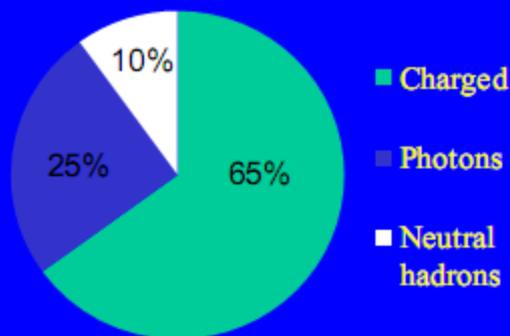

## Particle-Flow in a Nut-Shell

$$E(\text{jet}) = E(\text{charged}) + E(\text{photons}) + E(\text{neutral hadrons})$$

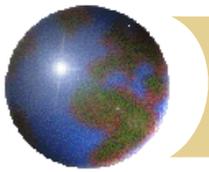

### Basics

- Outsource 65% of the event-energy measurement responsibility from the calorimeter to the tracker
  - Emphasize particle separability and tracking
  - Leading to better jet energy precision
- Reduce importance of hadronic leakage
  - Now only 10% instead of 75% of the average jet energy is susceptible
  - Detector designs suited to wide energy range
- Maximize event information
  - Aim for full reconstruction of each particle including V0s, kinks,  $\pi^0$  etc.
  - Facilitates software compensation and application of multi-variate techniques

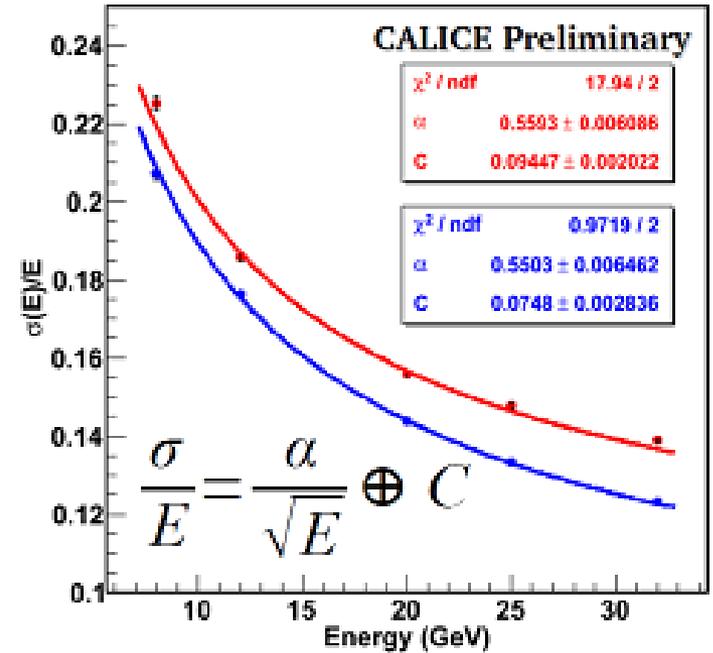

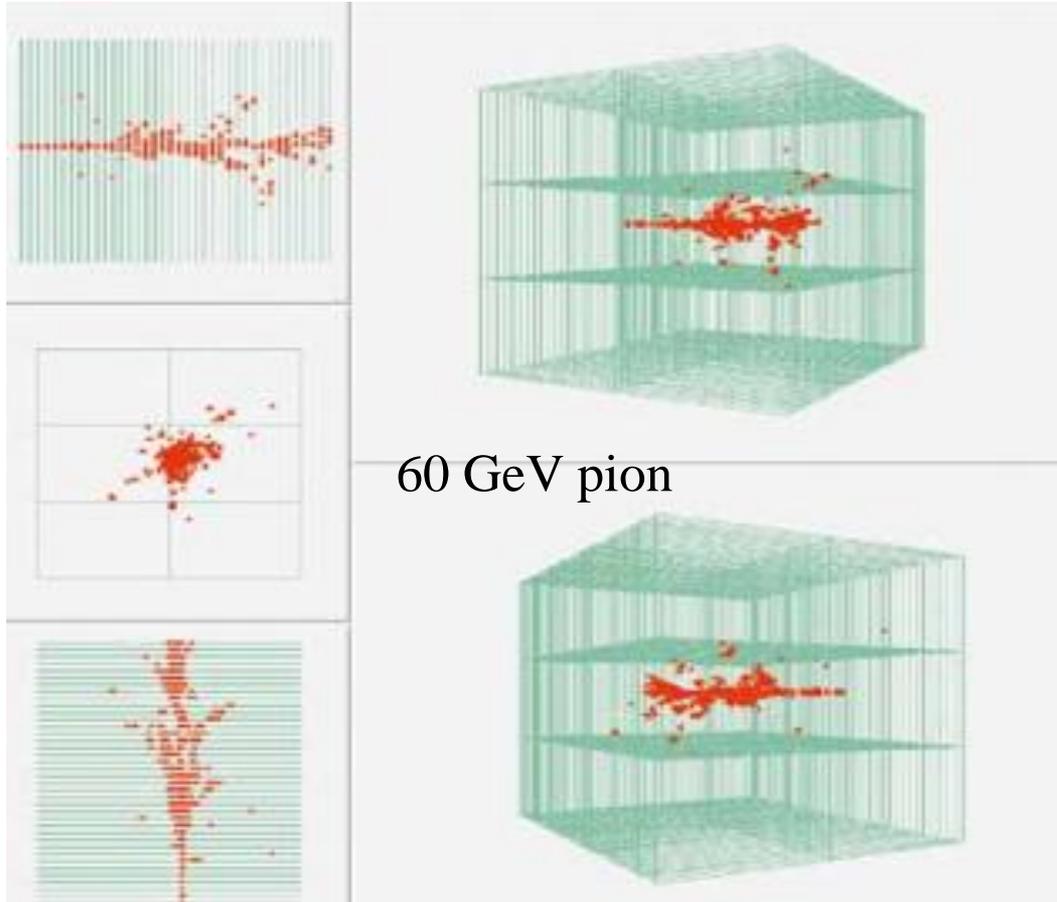

### Particle AVERAGES

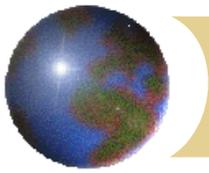

Tracking has a fractional momentum resolution that is  $\sim p$ , while calorimetry has a resolution that goes as a constant or as the inverse sqrt of the energy. Therefore, combine the measurements so that the best resolution obtains.

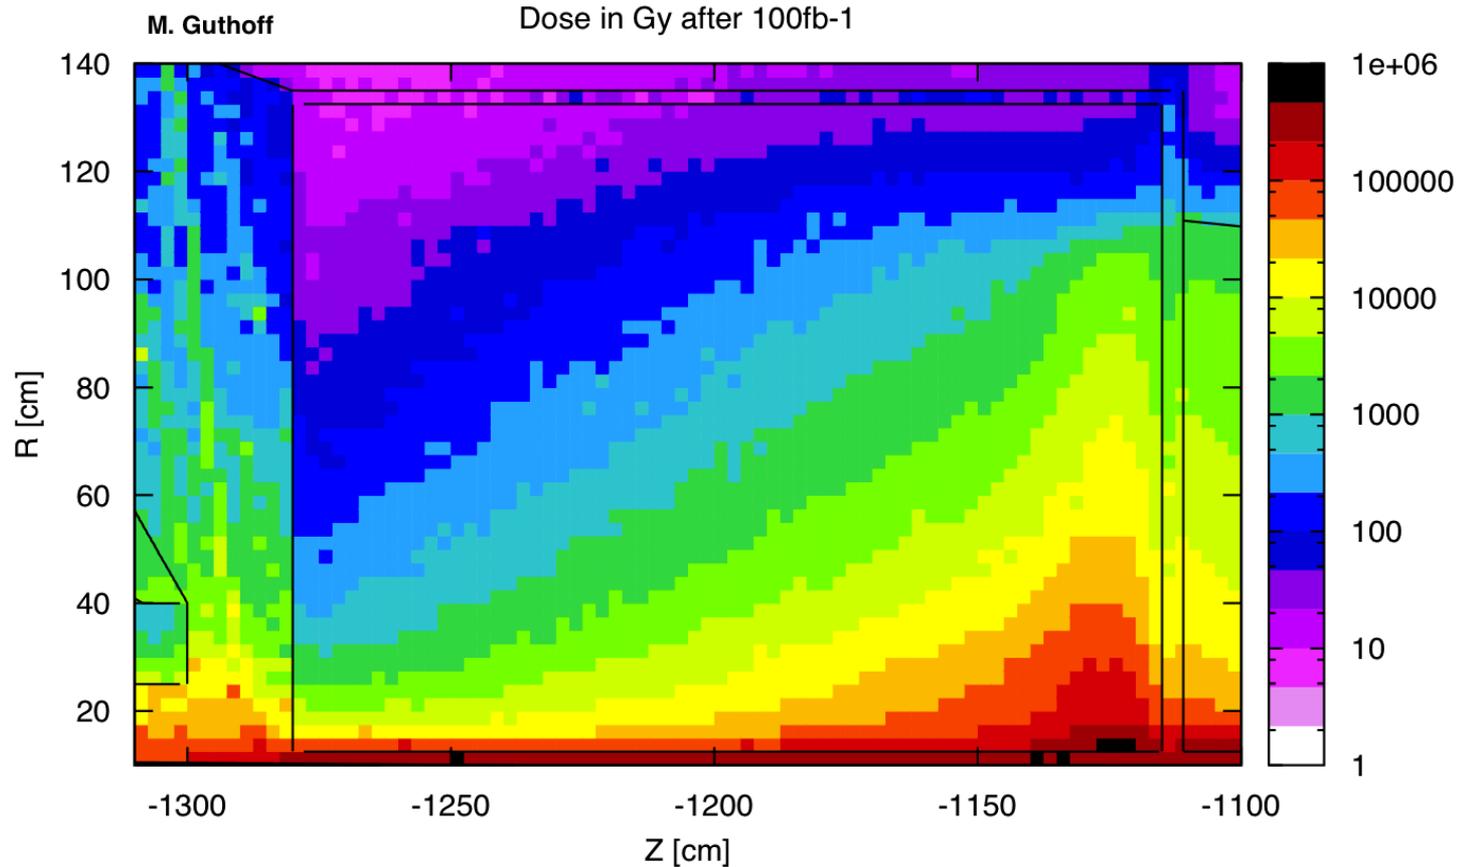

# DHC Calice

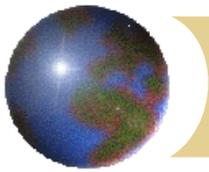

To match tracks to energy deposits very fine grained,  $dx \sim X_0 \sim dy \sim dz$ , calorimetry is needed. ILC prototypes are exploring these concepts.

# Radiation Dose - CMS

The radiation dose in hadron colliders requires radiation resistant detectors and front end electronics. This is a major problem at the SLHC.

# Neutrons

$$\sigma_I LTD_c (1 / 2\pi r_F^2) = 9.5 \times 10^{11} \pi^\pm / \text{cm}^2 \text{ yr}$$

At  $r = 1 \text{ m}$ .

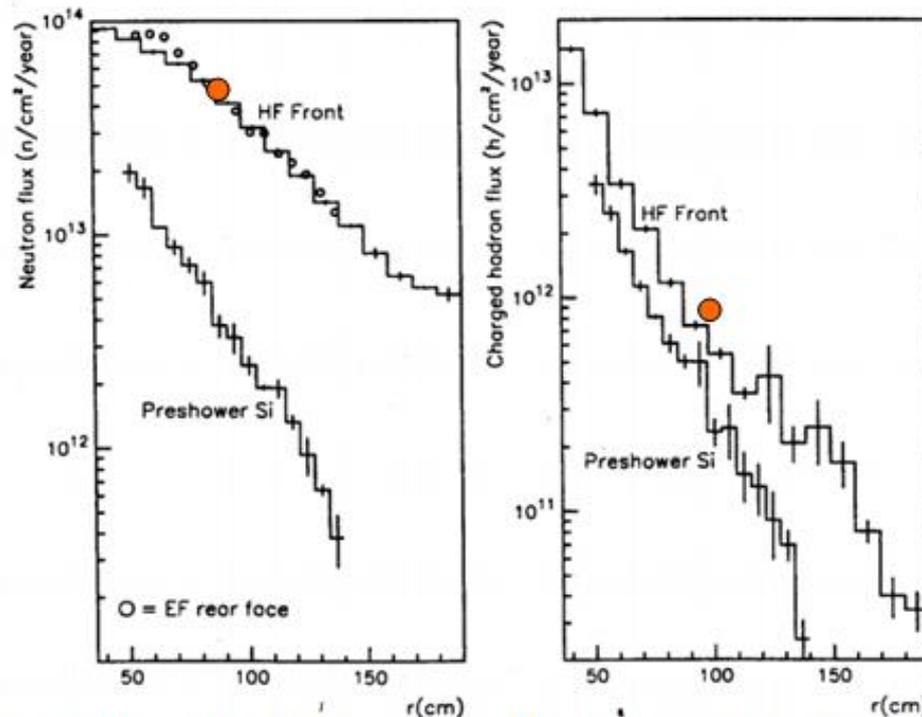

Figure 20: Charged particle flux, right, and neutron flux, left, as a function of radius for calorimetry at  $z = 10 \text{ m}$  [4].

Interactions in HCAL disrupt the nucleus – which de-excites and recoils – emitting neutrons. As a crude rule of thumb there are about 5 neutrons with a few MeV kinetic energy produced per GeV of absorbed hadrons.

$$3.82 \times 10^{13} \text{ n} / (\text{cm}^2 \text{ yr})$$

The intense n “sea” is ~ specific to hadronic detectors and is a serious rad issue.
